Abstract

Lyme borreliosis is a common tick-borne disease with a wide variety of clinical manifestations. Cardiac involvement has been reported during both the acute phase (atrioventricular block, pericarditis) and the chronic stage (dilated cardiomyopathy), but is rare (<5%). Here we describe the first case of Borrelia afzelii Lyme endocarditis, in a 61-year-old man living in an endemic area of France. The diagnosis was confirmed by detection of B. afzelii DNA in the mitral valve by specific real-time PCR. He was treated empirically with amoxicillin for 6 weeks and remains well 12 months later.

Keywords: B. afzelii, Borrelia, borreliosis, endocarditis, lyme

Lyme borreliosis (or Lyme disease) is the most commonly reported tick-borne disease in the northern hemisphere, notably in Europe and North America. The different species of the Borrelia burgdorferi sensu lato group are transmitted by infected ticks of the genus Ixodes. Whereas only one bacterial species, B. burgdorferi sensu stricto, is currently recognized as pathogenic in North America, several pathogenic species are present in Europe (mainly B. burgdorferi sensu stricto, B. afzelii and B. garinii), where they cause a wider variety of clinical manifestations [1]. Typically, following initial erythema migrans at the tick bite site, these bacteria can spread from the skin to other tissues and organs, causing more severe manifestations such as arthritis and cutaneous and neurological disorders [2]. Cardiac Lyme borreliosis is rare, representing only 0.3–4% of cases in Europe, and is generally associated with acute-onset atrioventricular (I–III) conduction disorders, arrhythmias and, in some cases, myocarditis or pericarditis [3–8]. Here we describe a documented case of Lyme endocarditis.

A 61-year-old man was admitted in March 2011 to Limoges University Hospital, France, for mitral valve replacement. He was an ex-smoker, had a history of paroxystic auricular fibrillation, and had mitral insufficiency due to mitral valve prolapse. Initial investigations showed auricular fibrillation and dyspnoea, mitral regurgitation with rope rupture, an ejection fraction of 45%, and a dilated left atrium on cardiac ultrasound. During surgery the macroscopic aspect of the mitral valve suggested endocarditis, with prolapse of the posterior valve and a 5-mm² perforation of the anterior valve. All blood cultures and serologies commonly performed in the case of endocarditis (Bartonella henselae, Bartonella quintana, Mycoplasma pneumoniae, Legionella pneumophila, Chlamydophila pneumoniae and Coxiella burnetii) were all negative. He was treated empirically with intravenous amoxicillin and gentamicin for 2 weeks, followed by oral amoxicillin for 4 weeks. Microscopic analysis of the mitral valve showed endocarditis with foamy macrophages suggestive of intracellular microorganisms (Photo I). Gram, PAS and Gimenez stains were negative. Whartin-Starry stain showed only...
scarce curved rods, which had a morphology that was not specific to Spirochaetes. Universal PCR targeting 16S RNA-encoding DNA was applied to a valve fragment and the amplification product was sequenced, identifying the genus *Borrelia*. Two valve fragments were sent to the French *Borrelia* National Reference Center for confirmation. Both were positive by specific real-time PCR using a Taqman® probe targeting a conserved region of the flagellin (*Fla*) gene of the *Borrelia burgdorferi sensu lato* (Bbsl) complex [9]. Further real-time DNA amplification using hybridization probes targeting species-specific regions of the *fla* gene identified *B. afzelii*. The Anti-*Borrelia* Plus VlsE ELISA IgG assay was positive and the Anti-*Borrelia* ELISA IgM assay was negative (both tests from Euroimmun AG, Luebeck, Germany). Western blot (*Borrelia afzelii* + VlsE Eco Blot IgG Western Blot; Virotech, Rüsselsheim, Germany) confirmed the presence of several antibodies targeting the VlsE, p83, p58, p39, p31 and p21 proteins. Only atrial fibrillation persisted after antibiotic treatment, with no mitral regurgitation. As the patient was well, and given the lack of specific therapeutic guidelines for Lyme endocarditis, antibiotic treatment was not prolonged or changed. The patient did not recall a tick bite, a previous episode of erythema migrans, or secondary manifestations such as meningoradiculitis.

To our knowledge this is the first documented case of *B. afzelii* Lyme endocarditis. In Europe, *B. afzelii* is commonly associated with neurological and late cutaneous manifestations, and less frequently with arthritis. Only one previous report described here emphasizes the need to perform universal PCR on heart valve samples in the case of endocarditis of unknown origin, and to bear in mind the possibility of bacterial aetiology in endemic areas.
